#### Lecture 28

### **Graphs**

- Notations and terminologies
- Data structures for graphs
- A few algorithmic problems in graphs

# Why Graphs ??

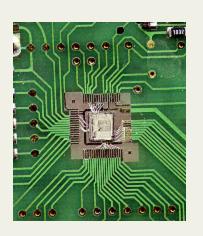

## Finding shortest route between cities

Given a network of **roads** connecting various cities, compute the <u>shortest route</u> between any two **cities**.

Just imagine how you would solve/approach this problem.

# Embedding an integrated circuit on mother board

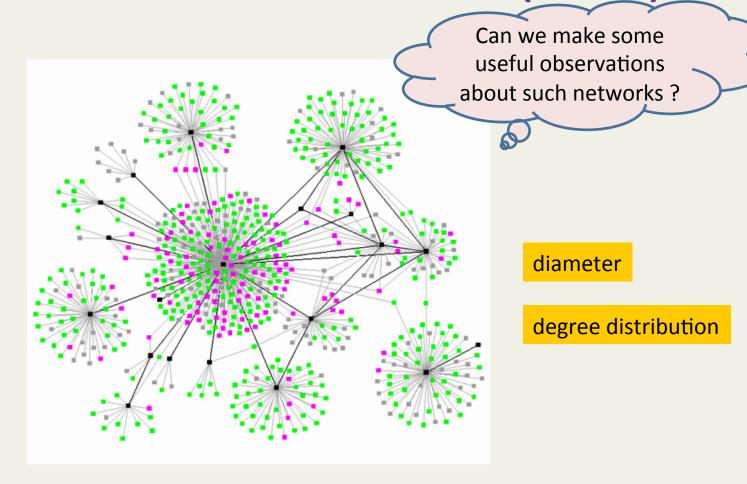

How to embed ports of various ICs on a plane and make connections among them so that

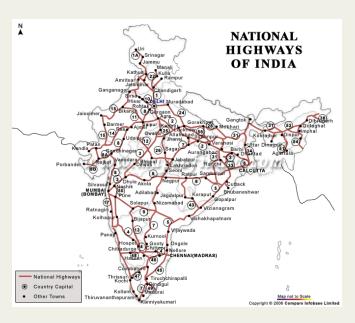

- No two connections <u>intersect</u> each other
- The <u>total length</u> of all the connections is <u>minimal</u>

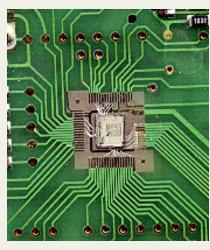

### A social network or world wide web (WWW)

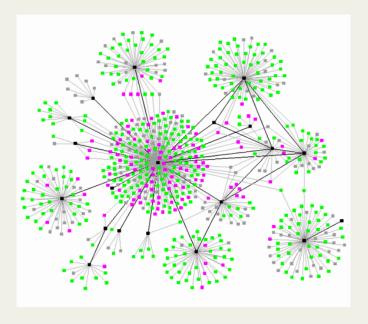

Do you know about the "6 degree of separation principle" of the world? Visit the site https://en.wikipedia.org/wiki/Six\_degrees\_of\_separation

### How will you model these problems?

### **Graph**

# Graph

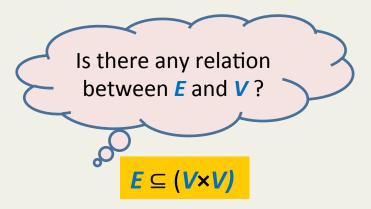

Definitions, notations, and terminologies

# Graph

A graph **G** is defined by two sets

• V: set of vertices

• E: set of edges

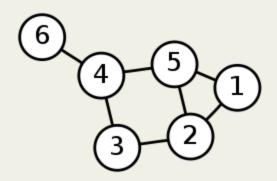

#### **Notation:**

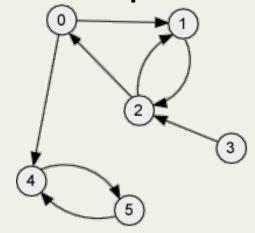

• A graph G consisting of vertices V and edges E is denoted by (V,E)

# **Types of graphs**

### **Undirected Graph**

### **Directed Graph**

### **Notations**

#### **Notations:**

```
• n = |v|
```

• m = |E|

**Note:** For directed graphs,  $m \le \frac{n(n-1)}{1}$ 

For undirected graphs,  $m \le \frac{n(n-1)/2}{11}$ 

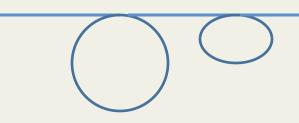

# Walks, paths, and cycles

#### Walk:

A sequence <, , ..., > of vertices

is said to be a **walk** from x to y

- =
- =
- For each ,  $(v \downarrow i, v \downarrow i + 1) \in E$

#### Path:

A walk <, , ..., > on which no vertex appears twice.

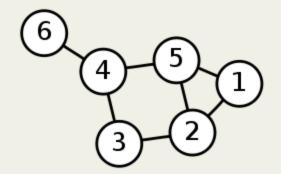

#### Cycle:

A walk <, , ..., > where no **intermediate** vertex gets repeated

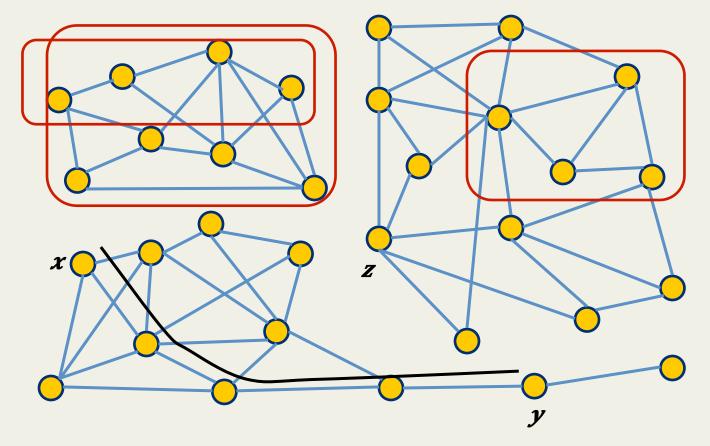

and =

# **Examples**

- <1,5,4> is a walk from 1 to 4.
- <1,3,2,5> is **not** a **walk**.
- <1,2,5,2,3,4,5,4,6> is a walk from 1 to 6.
- <1,2,5,4,6> is a path from 1 to 6.
- <2,3,4,5,2> is a cycle.

two vertices are said to be *connected* if there is a **path** between them

### **Connected component:**

A maximal subset of connected vertices

You can not add any more vertex to the subset and still keep it connected.

# **Data Structures for Graphs**

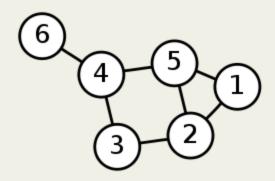

Vertices are always numbered

**1**,...,*n* 

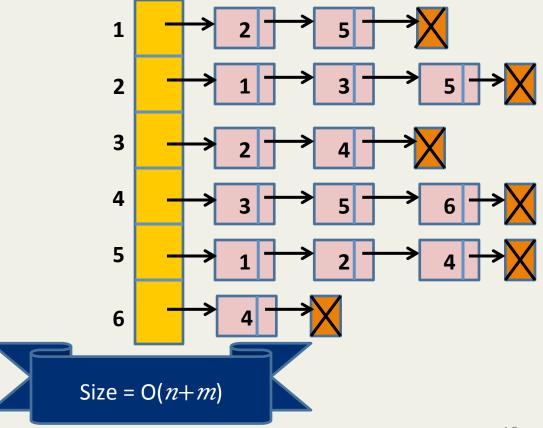

Or 0,...,*n*-1

# Link based data structure for graph

### **Undirected Graph**

### **Adjacency Lists**

### Link based data structure for graph

### **Advantage of Adjacency Lists:**

- Space efficient
- Computing all the neighbors of a vertex in <u>optimal time</u>.

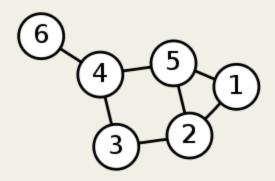

#### **Disadvantage of Adjacency Lists:**

How to determine if there is an edge from x to y?

 $(\mathbf{O}(\mathbf{M}))$  time in the worst case).

## Array based data structure for graph

### **Undirected Graph**

### **Adjacency Matrix**

	1	2	3	4	5	6
1	0	1	0	0	1	0
2	1	0	1	0	1	0
3	0	1	0	1	0	0
4	0	0	1	0	1	1
5	1	1	0	1	0	0
6	0	0	0	1	0	0

Size =  $O(n\hat{1}2)$ 

# Array based data structure for graph

#### **Advantage of Adjacency Matrix:**

• Determining whether there is an edge from x to y in O(1) time for any two vertices x and y.

### **Disadvantage of Adjacency Matrix:**

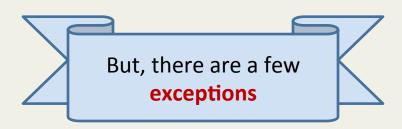

- Computing all neighbors of a given vertex x in O(n) time
- It takes  $\mathbf{o}(n2$  ) space.

# Which data structure is commonly used for storing graphs?

Adjacency lists

#### Reasons:

- Graphs in real life are sparse ().
- Most algorithms require <u>processing neighbors</u> of each vertex.
  - $\rightarrow$  Adjacency matrix will enforce  $\circ$ () bound on time complexity for such algorithm.

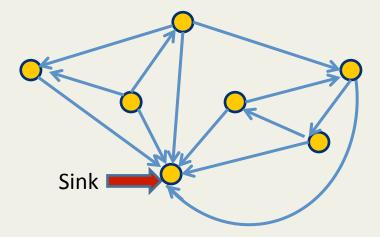

### An interesting problem

(Finding a sink)

A vertex x in a given directed graph is said to be a sink if

- There is no edge emanating from (leaving) x
- Every other vertex has an edge into x.

Given a directed graph G=(V,E) in an adjacency matrix representation, design an O(2) time algorithm to determine if there is any sink in G.

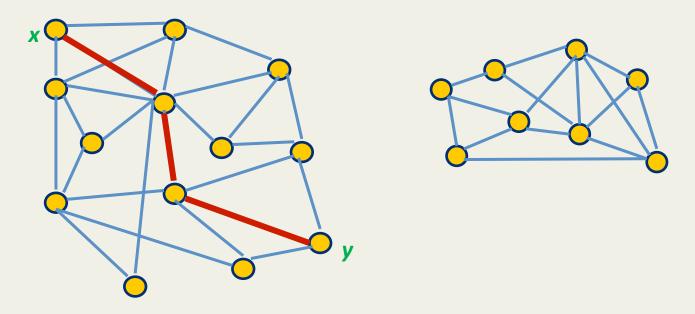

# **Graph traversal**

Topic for the next class

### **Graph traversal**

#### **Definition:**

A vertex y is said to be reachable from x if there is a path from x to y.

**Graph traversal from vertex** *x*: Starting from a given vertex *x*, the aim is to visit all vertices which are reachable from *x*.

## Non-triviality of graph traversal

### Avoiding loop:

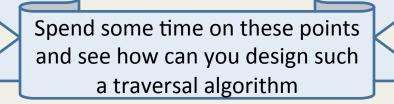

How to avoid visiting a vertex multiple times? (keeping track of vertices already visited)

### Finite number of steps :

The traversal **must stop** in finite number of steps.

#### Completeness:

We must visit all vertices reachable from the start vertex x.

### A sample of Graph algorithmic Problems

- Are two vertices  $oldsymbol{\mathcal{X}}$  and  $oldsymbol{\mathcal{Y}}$  connected ?
- Find all connected components in a graph.
- Is there is a cycle in a graph?
- Compute a path of shortest length between two vertices?
- Is there is a cycle passing through all vertices?
